

Micronutrients may help in Tinnitus-induced Hearing Loss

Tinnitus ("Tin-EYE-tus") is a symptom characterized by an auditory perception of noise or ringing in the ears. However, patients may also describe it as hissing, pulsing, whooshing, clicking or similar sounds. It is estimated that over 100 million adults worldwide are affected by tinnitus. It can disturb their daily lives with hearing loss, long-term sleep disturbances, changes in cognitive ability, challenges in employability and relationships, and can cause depression. Whilst anyone can develop this problem, tinnitus-induced hearing loss is the number one service-related disability for veterans and is expected to cost the US government over \$2.26 billion in compensation in 2014.

While the exact causes of tinnitus and consequent hearing loss are not clear, the most likely cause can be either a one-time or continuous exposure to loud noises which destroy the hair cells in the inner ear. Damaged hair cells are difficult to renew or replace. Tinnitus can also result from blockages in the ear canal from earwax or abnormal bone growth, anemia, high blood pressure or other blood vessel disorders, stress, head and neck injuries, or a benign tumor called acoustic neuroma. Over 200 medications including some antibiotics, painkillers, diuretics and chemotherapy drugs are known to cause hearing and balance problems as side effects. As the root cause of tinnitus is largely unknown, there is no effective treatment available for it within conventional medicine. Tinnitus-induced hearing loss is therefore mainly managed by hearing devices with less than satisfactory results.

Inflammation and oxidative damage to the cells lining the ear canal and the inner ear is one of the patho-mechanisms of tinnitus. As such, micronutrients such as vitamins C and E, glutathione, the B group of vitamins, Coenzyme Q-10, magnesium and others are known to protect various structures of the normal auditory apparatus.

We therefore conducted a pilot clinical trial to study the effect of a combination of micronutrients in patients suffering from tinnitus.* The patients were aged between 44 to 85 years old and had been suffering from tinnitus for more than three con-

secutive months. They all took a specifically designed micronutrient supplement. After four months on the micronutrient supplement program, 30% of the patients reported slight improvement in their hearing and 45% reported a clear improvement of 10-20 decibels. Twenty-five percent of the patients indicated a strong hearing improvement of up to 25-50 decibels, and a return of their normal hearing ability. More than 75% of the patients experienced some reduction in the ear ringing and for half of the patients the ear ringing almost completely disappeared.

Exposure to loud or continuous noise is a very common phenomenon in our modern society and most people are unaware of the long-term hearing implications. In addition to protecting the ears by avoiding noise exposure, wearing earplugs, and limiting the use of ear damaging medications, our studies show that supplementation with the appropriate micronutrients may provide relief to millions of people from tinnitus-induced hearing loss.

Health Science News Page

This information is provided to you courtesy of the Dr. Rath Research Institute. Led by two former colleagues of two-time Nobel Laureate Linus Pauling († 1994) this Institute has become a leader in the breakthrough of natural health research in the field of cancer, cardiovascular disease and other common diseases. The Institute is a 100% subsidiary of the non-profit Dr. Rath Foundation.

The groundbreaking nature of this research poses a threat to the multi-billion dollar pharmaceutical "business with disease." It is no surprise that over the years the drug lobby has attacked Dr. Rath and his research team in an attempt to silence this message. To no avail. During this battle, Dr. Rath has become an internationally renowned advocate for natural health saying, "Never in the history of medicine have researchers been so ferociously attacked for their discoveries. It reminds us that health is not given to us voluntarily, but we need to fight for it."
